REMAINING SITES VERIFICATION PACKAGE FOR THE 216-N-4 WASTE SITE LOCATED IN THE 200-CW-3 OPERABLE UNIT

EXECUTIVE SUMMARY

This report summarizes the successful completion of the remedial action conducted at the 216-N-4 waste site. This report demonstrates that the 216-N-4 waste site, following completion of the interim remedial action, meets the objectives for the selected remedy of removal, treatment and disposal (RTD) specified in the *Interim Action Record of Decision for the 100-BC-1*, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (Remaining Sites ROD) (EPA 1999).

The 216-N-4 waste site, also identified as the 216-N-4 Swamp, is included in the 200-CW-3 Operable Unit (OU) located in the 200 North Area of the Hanford Site. This pond received overflow cooling water from the 212-P Fuel Storage Facility. The field remedial action activities for the 216-N-4 waste site commenced with the initial site investigation in May 2009, progressed through RTD of contaminated soil, and concluded with verification sampling in August and September 2010. Evaluation of sampling results in October 2010 leads to the determination that, following completion of the remedial action, the site meets the remedial action goals (RAGs) and remedial action objectives (RAOs). Field work and determination of completion were conducted and performed in accordance with DOE/RL-2007-55, Remedial Design/Remedial Action Work Plan for 200 North Area Waste Sites located in the 200-CW-3 Operable Unit and DOE/RL-2007-54, Sampling and Analysis Plan for Remediation of 200 North Area Waste Sites Located in the 200-CW-3 Operable Unit.

The analytical results show that the residual soil concentration of contaminants of concern (COCs) supports the reasonably anticipated future land use recognized in the ROD and the RD/RAWP (for the purposes of this interim action, RAOs were selected that would support unrestricted land use). These results also support reclassification of the waste site to "interim closed out" in accordance with the process described in RL-TPA-90-0001, *Tri-Party Agreement Handbook Management Procedures*, Guideline Number TPA-MP-14, "Maintenance of the Waste Information Data System (WIDS)." Finalization of this report constitutes concurrence by the signing parties that the RAOs have been met, and thus backill and/or contouring may take place as described in Sections 3.1.2 and 3.1.5 of the RD/RAWP. Once the waste site has been

backfilled and/or contoured, native plant species will be seeded in each area, as applicable, as an interim step towards final revegetation, in accordance with Section 3.5.5 of the RD/RAWP. No institutional controls are required because no deep zone is associated with the 216-N-4 waste site.

This waste site and the data obtained from the subject sampling evolution will be included in the risk assessment and the remedial investigation and feasibility study for final remedial decisions of this area.

REMAINING SITES VERIFICATION PACKAGE FOR THE 216-N-4 WASTE SITE LOCATED IN THE 200-CW-3 OPERABLE UNIT

1.0 STATEMENT OF PROTECTIVENESS

When the removal, treatment, and disposal (RTD) action was selected for for the 216-N-4 Waste Site, soil with contaminant concentrations above RAGs was excavated to an approximate depth of 4.6 m (15 ft) below ground surface. (with deviations by agreement). Contaminant concentrations in the remaining soils were determined through the analysis of soil samples collected from the excavated waste sites and the comparison of the analytical results against established cleanup standards. The results of verification sampling following implementation of the RTD remedy at the 216-N-4 Waste Site demonstrate that the waste site meets the cleanup standards specified in the Interim Action Record of Decision for the 100-BC-1, 100-BC-2, 100-DR-1, 100-DR-2, 100-FR-1, 100-FR-2, 100-HR-1, 100-HR-2, 100-KR-1, 100-KR-2, 100-IU-2, 100-IU-6, and 200-CW-3 Operable Units, Hanford Site, Benton County, Washington (Remaining Sites Record of Decision [ROD]) (EPA 1999) and the Remedial Design/Remedial Action Work Plan for 200 North Area Waste Sites located in the 200-CW-3 Operable Unit (RD/RAWP) (DOE/RL-2007-55). Results summarized in this report demonstrate that residual COC concentrations in the soil in the 216-N-4 waste site area support unrestricted future use of shallow zone soil (i.e., surface to 4.6 meters (m) [15 feet (ft)]) and that contaminant levels remaining in the soil are protective of groundwater and the Columbia River. There is no deep zone for the 216-N-4 waste site. Therefore, no institutional controls are required.

The data resulting from this remedial action will be evaluated against the final clean-up standards developed for the Outer Area. Those standards are in development by way of two separate baseline risk assessments. A baseline risk assessment for the river corridor portion of Hanford began in 2004 and includes a more complete quantitative ecological risk assessment than was developed for the Remaining Sites ROD. Separately, an Ecological Risk Assessment is in development for the final remedial action for the Outer Area. Upon completion, the risk assessment for the Outer Area will include the 200-CW-3 Waste Sites (including 216-N-4) to support final remedial decisions.

2.0 GENERAL SITE INFORMATION AND BACKGROUND

The 200-CW-3 Operable Unit (OU) is located north of the 200 East and West Areas on the Hanford Site in the 200 North Area (Figure 1), Operations in the 200 North Area were primarily related to irradiated nuclear fuel storage. Fuel rods were stored in water filled basins while the decay of short-lived radioisotopes occurred (also known as "cooling"). The 200-CW-3 Waste Site Group includes areas of contamination resulting from the release of cooling water from the fuel storage basins.

The Waste Information Data System (WIDS) describes the 216-N-4 waste site as a pond that received overflow cooling water from the 212-P Fuel Storage Facility via a subgrade vitrified clay pipeline (600-286-PL). The dimensions provided by the WIDS data base for this waste site are 152.4 m (500 ft) long by 60.96 m (200 ft) wide, which yields a calculated surface area of 9,290.30 m² (100,000 ft²). The pond is situated 274 m (900 ft) south, southeast of the 212-P Building (shown in Figure 2), which has been demolished. The pond consisted of a natural depression in the terrain while in operation. The discharged water was dispersed via evaporation to the air and infiltration into the ground. Historical records indicate the site was deactivated in June 1952 and backfilled with 0.61 to 1.83 m (2 to 6 ft) of clean soil.

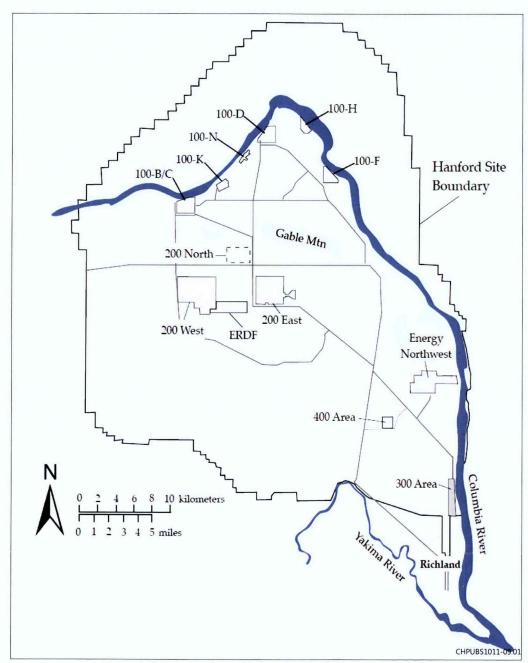

Figure 1. Location of the Hanford Site and the 200 North Area

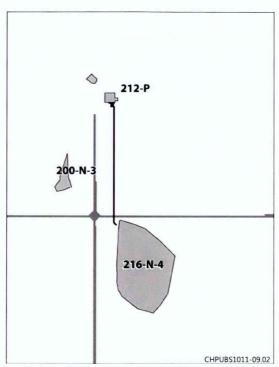

Figure 2. 216-N-4 Waste Site Location Map

3.0 SUMMARY OF REMEDIAL ACTION OBJECTIVES FOR THE 216-N-4 WASTE SITE

The analytical results from sampling evolutions (investigative and verification) of the 216-N-4 waste site indicate compliance with the remedial action goals (RAGs) and thus the remedial action objectives (RAOs) identified in the Remaining Sites ROD (EPA 1999) and the RD/RAWP (DOE/RL-2007-55). The RAOs provided in the Remaining Sites ROD and RD/RAWP are:

- RAO 1: Protect human and ecological receptors from exposure to contaminants in soils, structures, and debris by dermal exposure, inhalation or ingestion of radionuclides, inorganics, or organics.
- RAO 2: Control the sources of groundwater contamination to minimize the impacts to groundwater resources, protect the Columbia River from further adverse impacts, and reduce the degree of groundwater cleanup that may be required under future actions.

Table 1 provides a summary of the applicable regulatory requirements, the RAGs, the remediation results, and the attainment of the RAOs. Detailed sample analysis data are presented in Appendix G.

Table 1. Summary of Attainment of Remedial Action Objectives for the 216-N-4 Waste Site

Regulatory Requirement	Remedial Action Goals ^a	Results	Remedial Action Objectives Attained?
Direct Exposure – Radionuclides Attain total dose for radionut that does not exceed 15-mr above background over 1,000 years.		Residual concentrations of radionuclide COCs are less than one-tenth the single radionuclide soil concentration equivalent to a 15 mrem/year dose rate calculated by RESRAD. (Appendix A)	Yes
Direct Exposure – Reduce concentration of inorganics and organics to State of		All individual COC concentrations are below the direct exposure criteria. Results are presented in Appendix B.	Yes
Risk Requirements – Nonradionuclides	Contradionuclides		Yes
	10 ⁻⁶ for individual carcinogens.	naturally, was the only carcinogenic COC detected that required calculation of individual carcinogenic excess cancer risk (see Appendix B and Appendix G, Table G-2). The excess cancer risk calculated for hexavalent chromium meets the <1 x 10 ⁻⁶ criteria. See Appendix C for calculations.	
	Attain a cumulative excess cancer risk of <1 x 10 ⁻⁵ for carcinogens.	Hexavalent chromium, which does not occur naturally, was the only carcinogenic COC detected that required calculation of cumulative excess cancer risk (see Appendix B and Appendix G, Table G-2). The cumulative excess cancer risk calculated for these constituents meet the <1 x 10 ⁻⁵ criteria. See Appendix C for calculations.	
Groundwater/River Protection – Radionuclides	Attain single COC groundwater and river protection RAGs.	Maximum residual concentrations of radionuclide COCs were detected below groundwater and river protection exposure criteria (Appendix D). Values calculated by RESRAD that are protective of the groundwater are also protective of the Columbia River, since the contaminant pathway to the Columbia River is through the groundwater. NOTE: For uranium-233/234 and uranium-238, the groundwater MCL of 21.2 pCi/L corresponds to a soil concentration of 0.185 pCi/g. However, the Hanford specific background for these uranium isotopes is 1.1 pCi/g. The RAG therefore defaults to 1.1 pCi/g. (Appendix D, Footnote d)	Yes
	Attain national primary drinking water standards 4 mrem/yr (beta/gamma) dose rate to target receptor/organs.	Maximum residual concentrations of beta/gamma radionuclide COCs were detected below groundwater and river protection exposure criteria. (Appendix A, Footnote a)	

Table 1. Summary of Attainment of Remedial Action Objectives for the 216-N-4 Waste Site

Regulatory Requirement	Remedial Action Goals ^a	Results	Remedial Action Objectives Attained?
	Meet drinking water standards ^b for alpha emitters: the most stringent of 15 pCi/L MCL or 1/25th of the derived concentration guides from DOE Order 5400.5. ^c	Maximum residual concentrations of alpha emitting radionuclide COCs were detected below groundwater and river protection exposure criteria (Table 2 and Appendix D). RESRAD calculations predict that the only alpha-emitting radionuclide COCs with the potential to reach groundwater within 1,000 years are the uranium isotopes. NOTE: For uranium-233/234 and uranium-238, the groundwater MCL of 21.2 pCi/L corresponds to a soil concentration of 0.185 pCi/g. However, the Hanford specific background for these two uranium isotopes is 1.1 pCi/g. The RAG therefore defaults to 1.1 pCi/g. (Appendix D, Footnote d)	Yes
	Meet total uranium standard of 21.2 pCi/L. ^d	For uranium-233/234 and uranium-238, the groundwater MCL of 21.2 pCi/L corresponds to a soil concentration of 0.185 pCi/g (Appendix C). However, the Hanford specific background for these two uranium isotopes is 1.1 pCi/g. The RAG therefore defaults to 1.1 pCi/g. (Appendix D, Footnote d)	
Groundwater/River Protection – Nonradionuclides	Attain individual nonradionuclide groundwater and river cleanup requirements.	Maximum detected results for all nonradionuclides are below the RAGs for protection of groundwater (or RESRAD modeling predicts the COC will not reach groundwater within a 1,000 year time frame). (Appendix E)	Yes

Notes:

COC = contaminant of concern

MCL = maximum contaminant level (drinking water standard)

RAG = remedial action goal

RESRAD = RESidual RADioactivity

^a Remaining Sites ROD.

^c Radiation Protection of the Public and the Environment (DOE Order 5400.5).

^d Based on the isotopic distribution of uranium in the 100 Areas, 30 μg/L MCL corresponds to 21.2 pCi/L. Concentration-to-activity calculations are documented in *Calculation of Total Uranium Activity Corresponding to a Maximum Contaminant Level for Total Uranium of 30 Micrograms per Liter in Groundwater*, 0100X-CA-V0038 (BHI 2001).

4.0 WASTE SITE CHARACTERIZATION AND CONCEPTUAL MODEL SAMPLING

Initial investigative sampling was performed to determine the nature and extent of contaminants in the 216-N-4 waste site soils. These results served three primary purposes: (1) to confirm the selected remedy, (2) to support design of the RTD implementation, and (3) to support waste characterization and disposal. The waste site was characterized in accordance with the DOE/RL-2007-55, Remedial Design/Remedial Action Work Plan for 200 North Area Waste Sites located in the 200-CW-3 Operable Unit (RD/RAWP) and the DOE/RL-2007-54, Sampling and Analysis Plan for Remediation of 200 North Area Waste Sites Located in the 200-CW-3 Operable Unit (SAP). Soil sampling and analysis and radiological screening confirmed that RTD was the appropriate remedy selected for this site.

This section provides geophysical information for the area and waste site, the contaminants of concern (COCs) for the subject waste site, and a summary of the investigative sampling results as applicable to the development of the specific remedial action and verification sampling.

4.1 Geophysical Survey Results

The Hanford Site lies in a sediment-filled basin on the Columbia Plateau in southeastern Washington. The 200-CW-3 operable unit waste sites are located in the 200 North Area, which is situated on the 200 Areas Plateau north of a relatively flat prominent terrace (Cold Creek Bar), on a flood channel formed during the late Pleistocene flooding. The elevation in the vicinity ranges from approximately 180 m (593 ft) in the northern part of the unit to about 170 m (560 ft) above mean sea level in the southern part. There are no natural surface drainage features within the 200 North Area.

The vadose zone beneath the 200 Areas ranges in thickness from approximately 55 m (180 ft) beneath the former U Pond in the 200 West Area to approximately 104 m (341 ft) in the southern portion of the 200 East Area to approximately 49 m (160 ft) along the western part of the 200 North Area. Basalt of the Columbia River Basalt Group and a sequence of overlying sediments comprise the local geology. Sediments in the vadose zone consist primarily of the Hanford formation, Cold Creek unit/silt-dominated facies of the Cold Creek unit, and the Ringold Formation. The caliche or calcic facies of the Cold Creek unit is also present in the 200 West Area.

Groundwater beneath the Hanford Site is found in an upper primarily unconfined aquifer system and in deeper confined aquifers within the basalt. The Columbia River is the primary discharge area for both the unconfined and confined aquifers. The unconfined aquifer in the 200 North Area of the Central Plateau occurs in the Hanford formation. In general, groundwater flowing through the Central Plateau occurs in a predominantly easterly direction from the 200 West Area to the 200 East Area.

The nearest natural surface water body to the 200 North Area is West Lake (the 216-N-8 Pond) located approximately 0.8 km (0.5 mi) east. The potential for natural groundwater recharge within the 200 North Area is limited to precipitation infiltration. Estimates of recharge from precipitation at the Hanford Site range from 0 to 10 cm/yr (0 to 4 in/yr).

Waste Site 216-N-4 is a pond that received overflow cooling water from the 212-P Fuel Storage Facility via a pipeline (600-286-PL). The pond consisted of a natural depression in the terrain while in operation. The discharged water was dispersed by evaporation and infiltration into the ground. This site was associated with the 600-286-PL operational discharge line from 1944 through 1952 and, as a result, represents the potential time period the surface area soils could have been saturated. The pond was intermittently supplied with liquid discharged as gravity-fed overflow from the 212-P cooling basin during this time period. In addition, the absence of a recurring liquid discharge (or any known liquid discharge) to this area after 1952 would have restricted any additional drivers for vertical migration and

distribution of COCs through the sediments of the vadose zone other than the original operational discharges.

4.2 Contaminants of Concern

The COCs for the 216-N-4 waste site were identified based initially on historic/process information for the waste site and the contaminants of potential concern (COPCs) listed in the Remaining Sites ROD. Through the analytical results from the investigative sampling evolution, the COC list was developed and represents the full COPC list presented in the RD/RAWP and SAP. Table 2 provides the COCs for the 216-N-4 waste site.

Table 2. Contaminants of Concern for the 216-N-4 Waste Site

4.3 Waste Site Sample Design for Conceptual Model Confirmation and RTD Design

The nature of the 200-CW-3 OU waste sites supports the use of judgment/focused sampling for the waste site investigations, as identified in EPA/240/R-02/005, *Guidance on Choosing a Sampling Design for Environmental Data Collection* (EPA 2002). The function and discharge point of 216-N-4 pond was known. Investigative sampling was performed in a focused manner to determine the extent of contamination. Sampling was initiated at the location where effluent exited the discharge pipe and entered the pond (the northern most end of the waste site), which was expected to contain the highest concentration of COPCs. Sampling continued downgradient (with effluent flow) and laterally to identify the location that the COPCs were above action levels. Per the guidance in the RD/RAWP and SAP, samples were collected at depths below ground surface (bgs) (to a maximum of 15 ft bgs) to determine the vertical extent of contamination.

Due to the presence of radiological constituents in the discharge stream, radiological field surveys were an integral element of the investigative sampling evolution allowing real-time indication of the presence of COPCs (based on radiological indicators) during the sample collection activities.

Investigative sampling was performed May 22 through June 2, 2009. As shown in Figure 3, 20 sample locations were identified. Sample locations 1, 2, 3, 9, 12, 15, and 20 were targeted because they are located in the influent stream portion of the pond (lowest elevation) to define the extent of downgradient contamination from the point source. Sample locations 4 through 8, 10, 11, 17, and 19 were targeted to

define the lateral extent of contamination from the influent stream area. Following this rationale, additional sample locations would be developed based on sample results as needed.

The specific investigative sampling design for the 216-N-4 waste site was developed in accordance with the SAP, and follows the conceptual site model for surface spills developed under the remaining sites ROD. The conceptual model for surface spills includes the physical components and sample media at the site, sampling access, spatial boundaries and spatial distribution of contaminants.

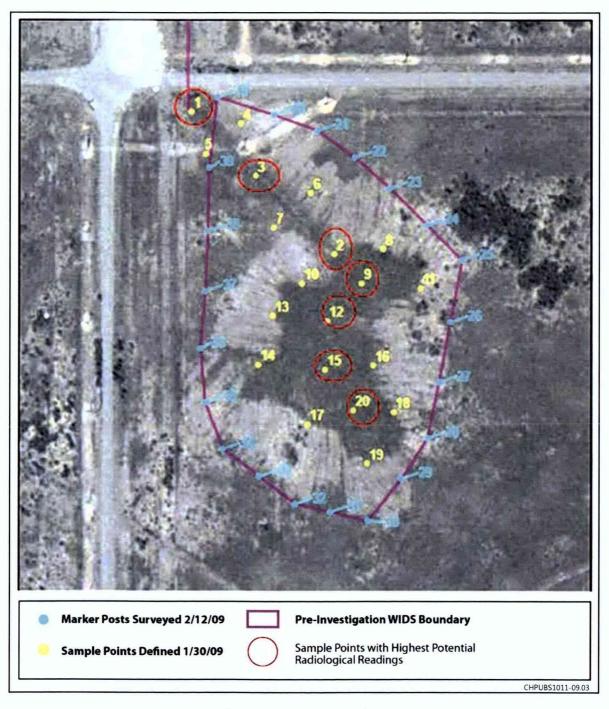

Figure 3. Aerial Image and Sample Locations

4.4 Sample Summary

Adhering to guidance prescribed in the SAP, discrete soil samples were collected at locations expected to contain the highest concentrations of COPCs based on historic/process knowledge and at locations showing radiological and/or visual indicators (such as soil staining). Radiological indicators (dose rate readings above background) were found at seven locations: sample locations 1, 3, 2, 9, 12, 15, and 20. Visual indicators (slight soil discoloration) were identified in sample location 1 at a depth of 3.1 m (10 ft) bgs.

Analytical results from investigative sampling are provided in Appendix F and provide the basis for transitioning from a listing of "potential" contaminants (COPCs), to the list of known contaminants (COCs). Two constituents (cesium-137 and europium-152) were found above action levels at various depths (0.6 to 4.6 m [2 to 15 ft] bgs) at one or more of the following sample locations: 1, 2, 3, 9, 12, 15, and 20. (Specific data results are provided in Appendix F). Contaminants at all other sample locations were below Look-Up Values. The results from the first phase of investigative sampling effectively identified and bounded the extent of the contaminated area to be subject to RTD and reduced the area originally attributed to the waste site to an area of 8,011 m² (86,229.68 ft²) (Figure 4).

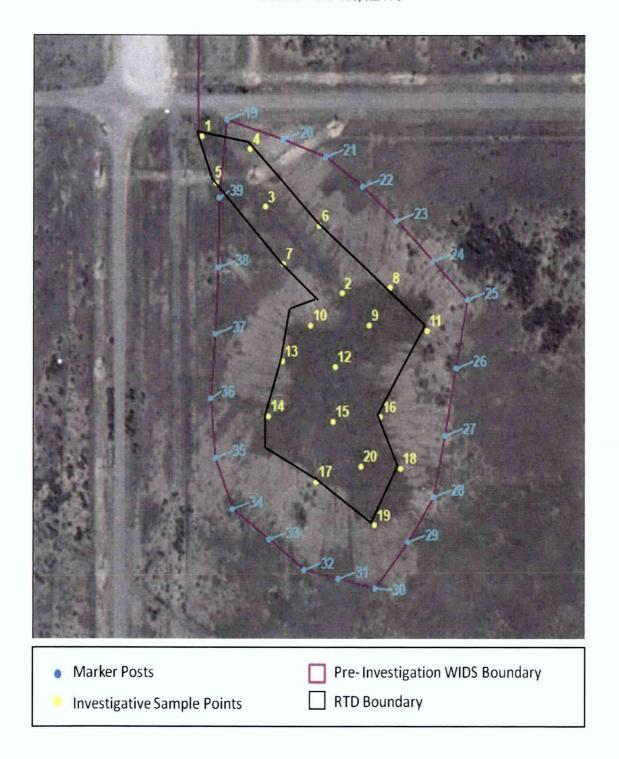

Figure 4. 216-N-4 RTD Area

5.0 WASTE SITE SAMPLING AFTER REMEDIATION ACTIVITIES

The selected remedy of RTD commenced at 216-N-4 waste site in December 2009 and was completed in July 2010. RTD activities involved the removal of contaminated soil from the 216-N-4 waste site and disposal at the Environmental Restoration Disposal Facility (ERDF).

The investigative sample findings provided the requisite information to commence excavation activities. As a result of plotting the investigative sample results, the extent of contamination became manifest, bounded by sample locations 4 through 8, 10, 11, 17, and 19 (shown in Figure 4). Radiological field screening provided real-time input to further guide the excavation, which aided in the identification and removal of contamination areas. The maximum vertical excavation depth was set at 4.6 m (15 ft) bgs.

The final excavation area was 7,430 m² (79,975.85 ft²) measured at ground surface with a slope of 1.5 to 1.0 (shown in Figure 5). The base (floor) of the excavation varied from roughly 1.25 m (4 ft) to 4.6 m (15 ft) in depth bgs. Approximately 32,951 metric tons (36,323 tons) of media (soil) were removed from the site and disposed of at ERDF.

Verification sampling was performed in August and September 2010. Laboratory analysis was performed to verify that remediation was complete and to demonstrate quantitatively that RAOs were met. The following sections provide a summary of the results of verification sampling and the attainment of RAOs.

5.1 Verification Sampling

Discrete samples were collected from the remediated area using a statistical sampling design. The number of samples and sample locations were determined using Visual Sample Plan[™] (VSP) software and a statistical sampling design with random start and 95% upper confidence limit. A map of sample locations is provided in Figure 5, with coordinates provided in Table 3.

Figure 5 shows the area of excavation. As described in the SAP, results from radiological field screening for detectable radiological contamination or cesium-137, an "indicator" constituent, conducted during excavation aided in defining the extent of the excavation area. Soil samples were collected as follows:

- Twenty verification samples (V-1 through V-20) were collected from the base and sidewalls of the excavation (samples were collected from surface soil (after excavation), where "surface" is 0 to 0.3 m [0 to 1 ft]).
- Five additional samples (V-3, V-7, V-12, V-15, and V-18) were collected at a depth of 15 ft below the original ground surface, in order to confirm that RAO 2 is met, and that analytical results are protective of groundwater.

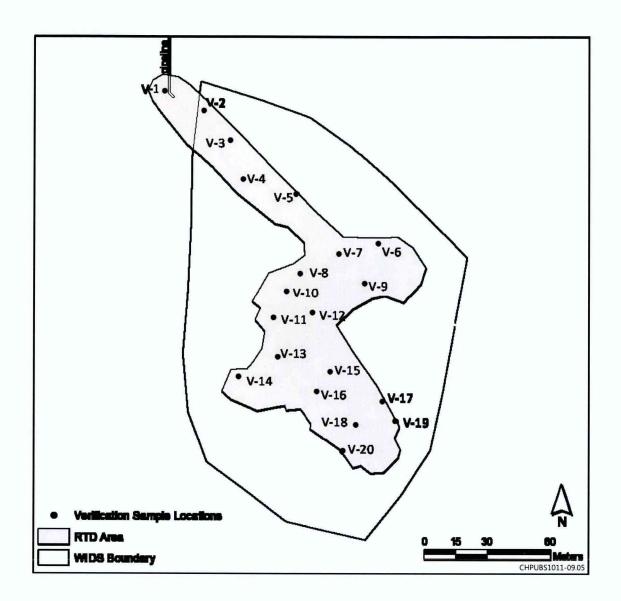

Figure 5. 216-N-4 RTD Area and Verification Sampling Locations

Verification sampling results were used to quantitatively demonstrate that residual concentrations of COCs remaining in the soil are below the RAGs and meet RAOs.

Appendix G provides photographs and analytical data for the 216-N-4 waste site verification sampling and analysis.

Table 3. GPS Coordinates for 216-N-4 Verification Sampling

5.2 Radiological Survey Field Screening

Radiological field screening was performed over the entire surface of the remediated area. Due to process knowledge of comingled radiological and chemical constituents, field screening for radiological contamination was used as an indicator to locate areas of chemical contamination. The survey was performed using standard radiological survey instruments in accordance with approved practices and procedures to obtain dose and contamination measurements with sufficient sensitivity to meet clean-up levels. Radiological screening was also performed of the samples themselves during the collection of focused samples.

Radiological field screening of the remediated surface and the sample collected indicated no detectable dose rates above background.

6.0 DATA EVALUATION

Results for the 216-N-4 waste site sampling and analysis for verification of remedy completion are provided in Appendix G. As shown in Table 4, all detected analytes were reported at concentrations below direct exposure, groundwater protection, and river protection RAGs, or below the Hanford Specific Background default value RAGs in the case of uranium-233/234 and uranium-238.

Nonradionuclide risk requirements for the 216-N-4 waste site include an individual and cumulative hazard quotient of less than 1.0, individual contaminant carcinogenic risks of less than 1 x 10⁻⁶, and a cumulative carcinogenic risk of less than 1 x 10⁻⁵. Risk values are not calculated for constituents that are either not detected or are detected at concentrations below Hanford Site or Washington State background values (Appendix G). Hexavalent chromium was detected in verification samples, but does not have a Hanford Site or Washington State background value. Risk calculations were conducted for hexavalent chromium based on the sample detections.

- The individual hazard quotients for noncarcinogenic constituents were less than 1.0. Hexavalent chromium was the only constituent used in the hazard quotient calculation. See Appendix C.
- The cumulative hazard quotient for all noncarcinogenic constituents was less than 1.0. Hexavalent chromium was the only constituent used in the hazard quotient calculation. See Appendix C.
- The individual carcinogenic risk values for carcinogenic constituents above background are all below 1 x 10⁻⁶. Hexavalent chromium was the only constituent used in the individual excess carcinogenetic risk calculation. See Appendix C.
- The cumulative excess carcinogenic risk values for carcinogenic constituents above background are all below 1 x 10⁻⁵. Hexavalent chromium was the only constituent used in the cumulative excess carcinogenetic risk calculation. See Appendix C.

7.0 DATA QUALITY ASSESSMENT

A data quality assessment (DQA) review was performed to compare the sampling approach and analytical data with the sampling and data requirements specified by the SAP (DOE/RL-2007-54). This review involves evaluation of the data to determine if they are of the right type, quality, and quantity to support the intended use (EPA 2000). The assessment review completes the data life cycle (i.e., planning, implementation, and assessment) that was initiated by the data quality process.

Level C data validation as defined in the contractor's validation procedures, which are based on EPA functional guidelines (e.g., *Laboratory Data Validation Functional Guidelines for Evaluating Inorganics Analyses* [Bleyler 1988a]; *Laboratory Data Validation Functional Guidelines for Evaluating Organics Analyses* [Bleyler 1988b]), was performed for the entire sampling and analysis data package for the investigative and verification samples collected for 216-N-4. Level C validation is a review of the quality control (QC) data and specifically requires verification of deliverables and requested versus reported analyses and qualification of the results based on: (a) analytical holding times, (b) method blank results, (c) matrix spike/matrix spike duplicate, (d) surrogate recoveries, (e) duplicates, and (f) analytical method blanks.

Specific data quality objectives for the site are found in the SAP (DOE/RL-2007-54). All samples were collected per the sample design described in Section 5.1. The COCs for 216-N-4 are in listed Table 2.

All of the sampling and analysis data generated from the investigative and verification sampling of 216-N-4 waste site is tracked through the following Hanford Environmental Information System (HEIS) numbers: B271F0, B271F1, B271F2, B271F4, B271N0, B271N1, B271N4, B271D9, B271H5, B271H6, B271H7, B271H8, B271J0, B27RT5, B27RT6, B27RT7, B27RT8, B27RT9, B27200, B27202, B27203, B27204, B27205, B27206, B27207, B27208, B271Y0, B271Y1, B27Y4, B271Y5, B271Y7, B271Y8, B271Y9, B271X8, B271X9, B27201, B271F8, B271F9, B271H0, B271H1, B271H3, B271W1, B271W2, B271W5, B271Y2, B271Y3, B271Y6, B271V7, B271V8, B271V9, B271W0, B271W3, B271W4, B271W6, B271W7, B271W8, B271X0, B271W9, B271X1, B271X3, B271X4, B271X5, B271X6, B271X7, equipment blanks: B27RV0, B27RV1, B272H5, B272H7, B272H9, B272H4, B272H6, B272H8, and trip blanks B27231, B272C0. All of the 216-N-4 sampling and analysis data were found to be useable for decision-making purposes as provided in the following summary:

HEIS Identification Numbers: B271F0, B271F1, B271F2, B271F4, B271N0, B271N1, B271N4, B271D9, B271H5, B271H6, B271H7, B271H8, B271J0, B27RT5, B27RT6, B27RT7, B27RT8, B27RT9, B27200, B27202, B27203, B27204, B27205, B27206, B27207, B27208, B271Y0, B271Y1, B27Y4, B271Y5, B271Y7, B271Y8, B271Y9, B271X8, B271X9, B27201, B271F8, B271F9, B271H0, B271H1, B271H3, B271W1, B271W2, B271W5, B271Y2, B271Y3, B271Y6, B271V7, B271V8, B271V9, B271W0, B271W3, B271W4, B271W6, B271W7, B271W8, B271X0, B271X1, B271X2, B271X3, B271X4, B271X5, B271X6, B271X7, equipment blanks: B27RV0, B27RV1, B272H5, B272H7, B272H9, B272H4, B272H6, B272H8, and trip blanks B27231, B272C0.

Blanks: Trip, field, equipment, and field transfer blanks with complete analyses were acceptable.

Field Duplicates: All duplicates were acceptable.

Matrix Spike/Matrix Spike Duplicate (MS/MSD) and Laboratory Control Standard/Laboratory Control Standards Duplicate (LCS/LCSD): MS/MSD and LCS/LCSD were run to an acceptable percentage recovery test as a result for calculation of relative percent difference (RPD) for QC purposes based on laboratory QA/QC procedures.

Radiochemistry, ICP Metals, PCB, and Chromium (VI) Analyses: Analytical reports were submitted for validation and verified for completeness based on the percentage of data determined to be valid (i.e., not rejected). The completion percentage was 100%. The data has been determined to be useable for decision-making purposes.

Field Screening: Relative to analytical data in sample media, physical data and/or field screening results are of lesser importance in making inferences of risk. Due to the secondary importance of such data, no validation for physical property data and/or field screening results was performed. However, field quality assurance/quality control (QA/QC) was reviewed to ensure that the data are useable. Field instrumentation, calibration, and QA checks were performed in accordance with the following:

- Calibration of radiological field instruments on the Hanford Site is performed under contract by Pacific Northwest National Laboratory, as specified in their program documentation.
- Daily calibration checks are performed and documented for each instrument used to characterize areas that are under investigation. These checks are made on standard materials that are sufficiently like the matrix under consideration that direct comparison of data can be made.

The review and approval of completed field radiation surveys by the radiological controls organization represents the data validation and usability review for handheld field radiological measurements.

The DQA review for these waste sites found the analytical results to be accurate within the standard errors associated with the methods, including sampling and sample handling. The data are of the correct type, quality, and quantity to support the intended use. Detection limits, precision, accuracy, and sampling data group completeness were assessed to determine if any analytical results should be rejected as a result of quality assurance and quality control deficiencies. All analytical data were found acceptable for decision-making purposes. All of the sampling analytical data are stored in the HEIS and are summarized in Appendix G. All qualifiers have also been added accordingly into the data for Appendix G.

8.0 SUMMARY SUPPORTING INTERIM CLOSED OUT RECLASSIFICATION

In August and September 2010, discrete soil samples were collected from the 216-N-4 waste site using a statistically based sampling approach with additional samples collected from locations judgmentally selected from process and sampling knowledge. The analytical results were compared to the Deep and

Shallow Zone Look-Up Values to determine whether further remediation was required. The analytical results from the soil samples are below the applicable Look-Up Values.

The analytical results from the soil samples meet the RAGs for direct exposure, groundwater protection, and river protection. In accordance with this evaluation, the sampling results support reclassification of the 216-N-4 waste site to 'interim closed out' status, as recorded on the Waste Site Reclassification Form, Control Number 2010-091. Per TPA-MP-14, 'interim closed out' status indicates that a waste site meets cleanup standards specified in the approved Remaining Sites ROD and related work plan(s), as an interim response action, but for which a Final Record of Decision has not been issued. Final remedial action evaluations and decisions for this waste site will be made under the final remedial action process for the Outer Area.

Finalization of this report constitutes concurrence by the signing parties that RAOs have been attained, thus backfill and/or contouring may take place, as described in Sections 3.1.2 and 3.1.5 of the RD/RAWP. Backfilling prior to finalization of this report may be necessary where worker safety or other issues warrant that action. Once the waste site has been backfilled and/or contoured, native plant species will be seeded in the area, as applicable, as an interim step toward final revegetation, in accordance with Section 3.5.5 of the RD/RAWP.

Table 4. Comparison of Maximum Soil Analyses to Remedial Action Goals for the 216-N-4 Waste Site ^a

	Hanford Site-		F	Remedial Action Go	oals	
Radiological Contaminant of Concern	Specific Background Activity (pCi/g)	Maximum Soil Analyses (pCi/g)	Direct Exposure (pCi/g)	Soil Cleanup Level for Groundwater Protection (pCi/g)	Soil Cleanup Level for River Protection (pCi/g)	Does the Maximum Exceed RAGs?
Americium-241	N/A	0.053 ^b	31.1	1,577,000	1,577,000	No
Cesium-137	1.1	3.4 b	6.2	NA ^c	NA ^c	No

Polychlorinated Biphenyls	N/A	U	0.5	NA ^c	NA ^c	No

Notes:

- ^a Site RAGs are taken from the RD/RAWP (DOE/RL-2007-55), where available, without further consideration of updated toxicity data or amendments (2004) to cleanup regulations in WAC 173-340.
- ^b The maximum cesium-137, europium-152, nickel-63, and plutonium-238 results exceed the Hanford Site-Specific background for the specific radionuclide. However, the RESRAD calculation predicts that cesium-137, europium-152, nickel-63, and plutonium-238 will not reach groundwater within 1,000 years based on the 100 Area generic site model using soil column layers and depths.
- c RESRAD predicts constituent will not reach groundwater within 1,000 years based on 100 Area generic site model using soil column layers and depths.
- d The remedial action goal is below the practical quantitation limit (PQL). The value presented is the PQL.
- The calculated soil concentration cleanup level of 0.185 pCi/g is below the Hanford Specific Background Activity of 1.1 pCi/g. Therefore the soil concentration protection of groundwater defaults to 1.1 pCi/g.
- Where cleanup levels are less than background or required detection limit (RDLs), cleanup levels default to background or RDLs per Ecology 1996, WAC 173-340-700(4)(d) and WAC 173-340-707(2), respectively. The arsenic cleanup level of 20 mg/kg has been agreed to by the Tri-Party Agreement Project Managers Managers (the basis is documented in DOE/RL-96-17, Rev 5, 2.1,2.1).

Abbreviations: NA = Not Applicable (see note c above)

N/A = Not Available

RAG = Remedial Action Goal

U = Analyte was not detected above detection limits. Detection limits are below RAGs.

9.0 SUMMARY OF PROJECT COSTS

For the purposes of reporting costs of remedial action for the 216-N-4 waste site, costs are pro rated utilizing an activity/schedule-based methodology. This method is not considered to be audit quality data. Actual costs for waste site clean up will continue to be collected for each operable unit or closure area in accordance with the current cost tracking methodology. These costs will then be included, in accordance with CERCLA requirements, in the remedial action report for the final remedial action of the operable unit or closure area. Table 5 provides the cost summary.

Table 5. Cost Summary

		Cost Item	Actual Cost FY 2009 (\$\$)	Actual Cost FY 2010 (\$\$)	Actual Total Cost (\$\$)
RA C	apita	al (Construction) Costs	0	0	0
RA O	pera	ating Costs	\$150,200	\$1,999,700	\$2,149,900
Total RA Cost		Cost	\$150,200	\$1,999,700	\$2,149,900
Projec	cted	Yearly O&M Cost	0	0	0
FY	=	fiscal year			
O&M	=	operation and maintenance			
RA	=	remedial action

Appendix C

Hazard Quotients and Excess Carcinogenic Risk

APPENDIX C

PURPOSE:

Provide documentation to support the calculation of the hazard quotient (HQ) and carcinogenic (excess cancer) risk values for the 216-N-4 waste site remedial action. In accordance with the remedial action goals (RAGs) in the *Remedial Design/Remedial Action Work Plan for 200 North Area Waste Sites located in the 200-CW-3 Operable Unit* (DOE/RL-2007-55), the following criteria must be met:

- 1) An HQ of <1.0 for all individual noncarcinogens
- 2) A cumulative HQ of <1.0 for noncarcinogens
- 3) An excess cancer risk of $<1 \times 10^{-6}$ for individual carcinogens
- 4) A cumulative excess cancer risk of <1 x 10⁻⁵ for carcinogens

GIVEN/REFERENCES:

DOE/RL-2007-55, Remedial Design/Remedial Action Work Plan for 200 North Area Waste Sites located in the 200-CW-3 Operable Unit, Rev. 0, U.S. Department of Energy, Richland Operations Office, Richland, Washington.

WAC 173-340, "Model Toxics Control Act - Cleanup," Washington Administrative Code, 1996.

SOLUTION:

- 1) Calculate an HQ for each noncarcinogenic constituent detected above background and compare it to the individual HQ of <1.0 (DOE/RL-2007-55).
- 2) Sum the HQs and compare to the cumulative HQ criterion of <1.0.
- 3) Calculate an excess cancer risk value for each carcinogenic constituent detected above background and compare it to the individual excess cancer risk criterion of $<1 \times 10^{-6}$ (DOE/RL-2007-55).
- 4) Sum the excess cancer risk values and compare to the cumulative cancer risk criterion of $<1 \times 10^{-5}$.

METHODOLOGY:

Hazard quotient and carcinogenic risk calculations were computed using the data from Appendix G, Table G-2. Of the contaminants of concern listed in Appendix G, Table G-2, hexavalent chromium was the only analyte detected which required the HQ and risk calculations. An explanation of the HQ and risk calculations follows.

- 1) For example, the maximum value for hexavalent chromium is 0.155 mg/kg; when divided by the RAG value of 240 mg/kg, the result is 0.000646. Comparing this value to the requirement <1.0, this criteria is met.
- 2) After the HQ calculations are completed for the appropriate analytes, the cumulative HQ is obtained by summing the individual values and comparing the resulting value to the requirement of <1.0.
- 3) To calculate the excess cancer risk, the maximum value is divided by the carcinogenic RAG value, then multiplied by 1 x 10⁻⁶. Three constituents in the COC list are carcinogens: arsenic, cadmium, and

hexavalent chromium. Because analytical data for arsenic indicate results below background and results for cadmium indicate undetectable concentrations in the sampled soil, the cumulative excess cancer risk is not applicable. Results for hexavalent chromium showed levels that are detectable. There is no background value for hexavalent chromium; thus, the risk is evaluated below.

RESULTS:

- 1) List individual noncarcinogens and corresponding HQs >1.0: None.
- 2) List the cumulative noncarcinogenic HQ >1.0: None.
- 3) List individual carcinogens and corresponding excess cancer risk >1 x 10⁻⁶: None.
- 4) List the cumulative excess cancer risk for carcinogens $>1 \times 10^{-5}$: None.

Table C-1 shows the results of the calculation:

Table C-1. Hazard Quotient and Excess Cancer Risk Results

Contaminants of Concern	Maximum Value ^a (mg/kg)	Noncarcinogen RAG ^b (mg/kg)	Hazard Quotient	Carcinogen RAG (mg/kg)	Carcinogen Risk
Metals					
Chromium (VI)	0.155	240	0.000646	2.1	7.38 x 10 ⁻⁸
Totals					
Cumulative Hazard Quotient:		==	0.000646		
Cumulative Excess Cancer Risk					7.38 x 10 ⁻⁸

Notes:

RAG = Remedial Action Goal

CONCLUSION:

This calculation demonstrates that the 216-N-4 waste site meets the requirements for the hazard quotients and carcinogenic (excess cancer) risk as identified in the RD/RAWP (DOE/RL-2007-55).

a. From Appendix G, Table G-2a.

b. Value obtained from Washington Administrative Code (WAC) 173-340-740(3), Method B, 1996, unless otherwise noted.

Appendix D

Comparison of Maximum Sample Analyses to Soil Activities Calculated by RESRAD to be Protective of 100 Area Groundwater

APPENDIX D

Table D-1 shows the comparison of the maximum sample analyses to the soil activities calculated by RESRAD.

Table D-1. Comparison of Maximum Sample Analyses to Soil Activities Calculated by RESRAD to be Protective of 100 Area Groundwater

Radionuclide	Groundwater MCL ^a (pCi/L)	Soil Concentration Protective of Groundwater ^b (pCi/g)	Maximum Results (pCi/g)
Americium-241	1.2	1,577,000	0.053

Uranium-235	21.2	1.0	0.028 (<bg)< td=""></bg)<>
Uranium-238	21.2	1.1 ^d	0.22 (<bg)< td=""></bg)<>

Notes:

- a. MCL = Maximum contaminant level calculated from National Bureau of Standards (NBS Handbook 69) maximum permissible concentration (MPC) as cited in EPA/540-R-00-007, the RAG from the RD/RAWP (DOE/RL-2007-55), or the MCL from 40 CFR 141.66.
- b. From DOE/RL-2007-55, Remedial Design/Remedial Action Work Plan for 200 North Area Waste Sites Located in the 200-CW-3 Operable
- c. RESRAD predicts constituent will not reach groundwater within 1,000 years based on 100 Area generic site model using soil column layers and depths.
- d. The calculated soil concentration cleanup level of 0.185 pCi/g is below the Hanford Specific Background Activity of 1.1 pCi/g. Therefore the soil concentration protection of groundwater defaults to 1.1 pCi/g.
- U = Analyte not detected above detection limits. Detection limits below RAGs.
- <BG= Less than background

Appendix E

Summary of Comparison of Maximum Sample Analyses to 100 Area Nonradionuclide Cleanup Levels for Protection of Groundwater and the Columbia River

APPENDIX E

Table E-1 provides a comparison of the maximum sample analyses to the 100 Area nonradionuclide cleanup levels established to protect groundwater and the Columbia River.

Table E-1. Summary of Comparison of Maximum Sample Analyses to 100 Area Nonradionuclide Cleanup Levels for Protection of Groundwater and the Columbia River

	Soil Cleanup Lev	els (mg/kg)	
Contaminant <i>Metals</i>	Protective of Groundwater	Protective of the Columbia River	Maximum Results (mg/kg)

PCBs	0.5	NA	U	U	U	U	U	U

a. In the shallow zone, cleanup must achieve the direct exposure remedial action objectives (RAO) and the groundwater/Columbia River RAO; therefore, the lowest value among the "Protection from Direct Exposure,"

NA = Not Available

PCB = Polychlorinated biphenyls

[&]quot;Protective of Groundwater," and "Protective of the Columbia River" values is the applicable look-up value.

b. The remedial action goal is below the practical quantitation limit (PQL). The value presented is the PQL.

c. Hanford-specific background not available; therefore values were taken from *Natural Background Soil Metals Concentrations in Washington State*, Publication No. 94-115, Washington State Department of Ecology, Olympia, Washington (Ecology 1994).

d. The remedial action goal is below background. The value presented is background.

e. Samples were analyzed for Total Chromium and Chromium (VI). The concentration for Chromium (III) is obtained by subtracting the concentration of Chromium (VI) from the concentration of Total Chromium.

Appendix G

Verification of Remedy Completion Data Summary

APPENDIX G

This appendix provides a data summary of the verification sampling data (Table G-1 and G-2). The view of sampling locations, shown in Figure G-1 below, are facing towards the southeast.

Figure G-1. 216-N-4 Verification Sampling Locations

NOTE: Field work was performed based on investigative sample data and historical knowledge, with consideration of radiological and hazardous contaminant concerns. Field screening of contaminants confirmed planning assumptions and ensured protection of personnel.

Figure G-2. 216-N-4 Verification Depth Sampling

NOTE: Field work was performed based on investigative sample data and historical knowledge, with consideration of radiological and hazardous contaminant concerns. Field screening of contaminants confirmed planning assumptions and ensured protection of personnel.

a. In the shallow zone, cleanup must achieve the direct exposure remedial action objectives (RAO) and the groundwater/Columbia River RAO; therefore, the lowest value among the "Protection from Direct Exposure," "Protective of Groundwater," and "Protective of the Columbia River" values is the applicable look-up value.

NA = Not Available

b Unless otherwise noted, background concentrations are 90th percentile values of the log normal distribution of the site-wide solid background data. Source: Hanford Site Background: Part 1 Soil Background for Nonradionuclide Analytes (DOE/RL-92-24).

^c Detection limits are taken from DOE/RL-2007-54 unless otherwise noted.

^d Surface is 0 to 0.3 m (0 to 1 ft) at the base of the excavation and 4.67 m (15 ft) is from original grade.

e The remedial action goal is below the practical quantitation limit (PQL). The value presented is the PQL.

f The remedial action goal is below background. The value presented is background.

g Hanford-specific background not available; therefore values were taken from Natural Background Soil Metals Concentrations in Washington State, Publication No. 94-115, Washington State Department of Ecology, Olympia, Washington (Ecology 1994).

h Samples were analyzed for Total Chromium and Chromium (VI). The concentration for Chromium (III) is obtained by subtracting the concentration of Chromium (VI) from the concentration of Total Chromium.

a In the shallow zone, cleanup must achieve the direct exposure remedial action objectives (RAO) and the groundwater/Columbia River RAO; therefore, the lowest value among the "Protection from Direct Exposure," "Protective of Groundwater," and "Protective of the Columbia River" values is the applicable look-up value.

NA = Not Available

b Unless otherwise noted, background concentrations are 90th percentile values of the log normal distribution of the site-wide solid background data. Source: Hanford Site Background: Part 1 Soil Background for Nonradionuclide Analytes (DOE/RL-92-24).

^c Detection limits are taken from DOE/RL-2007-54 unless otherwise noted.

d Surface is 0 to 0.3 m (0 to 1 ft) at the base of the excavation and 4.67 m (15 ft) is from original grade.

[•] The remedial action goal is below the practical quantitation limit (PQL). The value presented is the PQL.

f The remedial action goal is below background. The value presented is background.

⁹ Hanford-specific background not available; therefore values were taken from Natural Background Soil Metals Concentrations in Washington State, Publication No. 94-115, Washington State Department of Ecology, Olympia, Washington (Ecology 1994).

h Samples were analyzed for Total Chromium and Chromium (VI). The concentration for Chromium (III) is obtained by subtracting the concentration of Chromium (VI) from the concentration of Total Chromium.
